### 3 Computational considerations

- In what follows, we analyze the complexity of the Simplex algorithm more in detail
- For this purpose, we focus on the update process in each iteration of this procedure
- Clearly, since, up to now, the illustration of the algorithm was the primary aim, we updated the Tableau completely
- However, if we code the algorithm in some computer language this is not efficient
- Therefore, we introduce the so-called revised Simplex algorithm

impeter	School	1
	1	1445

Business Computing and Operations Research WINFOR 328

### 3.1 The Revised Simplex Algorithm

- By considering the Simplex Algorithm generated above, it turns out that we have to update a complete (m+1)x(n+1) tableau throughout the calculation process
- Additional analyses, however, show that we can reduce this effort by keeping a significantly smaller (m+1)x(m+1) tableau
- Specifically, this is established by making use of the following scheme

Business Computing and Operations Research WINFOR 329

### **Basic observations**

- If we commence our calculations with the identity matrix  $E_m$ , we finally obtain the inverted matrix of  $A_B$ corresponding to a current basis B
- Thus, we start with a zero cost row as the objective function. This enables us to determine the corresponding dual solution
- Since c is given as a parameter, we can identify the relative costs by using a simple transformation
- At iteration *I*, we denote the considered (m+1)x(m+1)matrix as CARRY(1)
- In addition, we commence the calculation with CARRY(0)

### Thus, we work with the following tableau

### **Transformations**

- Additionally, we keep track of the basis B, i.e., the current basic variables that form the current bfs
- In order to carry out the Primal Simplex Algorithm, the following steps are necessary
- 1. Generate the relative costs  $\overline{c}_i = c_i \pi^T \cdot a^j$  one at a time until we either find a negative - say for j = s - value or we terminate with the cognition that the current solution is optimal already

Business Computing and Operations Research WINFOR 332

### **Transformations**

2. Column Generation:

Generate the column  $\overline{a}^s = A_B^{-1} \cdot a^s \Rightarrow$  Generate the pivot

element 
$$r$$
 with  $\frac{\overline{b}_r}{\overline{a}_{r,s}} = \min \left\{ \frac{\overline{b}_p}{\overline{a}_{p,s}} \mid p \in \{1,...,m\} \land \overline{a}_{p,s} > 0 \right\}$ . Clearly,

if r does not exist, the problem is unbounded.

- 3. Update  $CARRY^{(l)}$  to obtain  $CARRY^{(l+1)}$ . By making use of vector  $\overline{a}^s$ , we are able to update  $A_B^{-1}$  and  $\overline{b}$  accordingly.
- 4. Update the basis B accordingly. Specifically, we replace B(r)by *s*.

### Column generation

- The second step introduces new columns, i.e., a new alternative in the tableau
- . By making use of the inverted matrix of the current  $A_{\rm B}$ , we can iteratively generate the columns of the original primal tableau
- In step 3, we apply all updating operations to the inverted matrix as well as to the left-hand side, i.e., to  $\overline{b} = A_{\scriptscriptstyle R}^{\scriptscriptstyle -1} \cdot b$

Business Computing and Operations Research WINFOR 334

### **Applied to the Two-Phase Method**

- Note that applying the Revised Simplex to the Two-Phase Method comes along with several specifics we must attend to
- First of all, the initial solution coincides with the maximal usage of the *m* auxiliary variables (for every row one variable)
- Hence, the inverted matrix  $A_B^{-1}$  is
- In order to commence with correct cost values for the column j that does not belong to the basis, we determine

$$\overline{c}_{j} = -\sum_{i=1}^{m} a_{i,j} - \pi^{T} \cdot a^{j}$$

• For the second phase, we have to adjust the objective function

$$-\pi^T = -c_B^T \cdot A_B^{-1}$$

Business Computing and Operations Research WINFOR 335

### The Revised Primal Simplex Algorithm I

In what follows, we assume that the right hand side b is positive. If this does not apply we have to use the two-phase method instead

- Transform the primal problem into canonical form. Generate equations with the slack variables denoted as  $x_1,\dots,x_m$  and let  $x_{m+1},\dots,x_{m+n}$  be the structure variables. Obtain a minimization objective function.
- 2. Start with the feasible basic solution to the primal problem given by the slack variables: Obtain  $\overline{b}=b,\pi^T=0$  and  $A_B^{-1}:=E_m,B(1)=1,\ldots,B(m)=m$
- 3. Search for a pivot column  $s := \min \left\{ j \middle| \overline{c}_j = c_j \pi^T a^j < 0 \right\}$ 
  - Calculate  $\overline{a}^s := A_B^{-1} \cdot a^s$ .
  - If  $\forall i = 1,...,m : \overline{a}_{is} \le 0$ , then terminate since the solution space is unbounded.
  - Pivot row r:  $\lambda_0 := \min\{\overline{b_i}/\overline{a_{is}} | \forall i = 1,...,m : \overline{a_{is}} > 0\}$  that is an upper bound on  $x_s$ .

### The Revised Primal Simplex Algorithm II

- $$\begin{split} P = & \left(e^1, ..., \underbrace{p^r_{Column\ r}}_{Column\ r}, ..., e^m\right) \text{ with } \left(p^r\right)^T = \left(p_{1r} := -\frac{\overline{a}_{1s}}{\overline{a}_r}, ..., p_{rr} := \frac{1}{\overline{a}_r}, ..., p_{mr} := -\frac{\overline{a}_{ms}}{\overline{a}_r}. \end{split}$$
    $\bullet \quad \text{Basis change } (\mathbf{x}_s \text{ enters the basis and } \mathbf{x}_{\mathsf{B}(t)} \text{ becomes a non-basic variable}) \\ \quad \text{Calculate } A_B^{-1} := P \cdot A_B^{-1} \text{ and set } \mathbf{B}(t) := \mathbf{s} \\ \quad \text{Calculate } \overline{b} := A_B^{-1} \cdot b, \pi^T := c_B^T \cdot A_B^{-1} \\ \quad \bullet \quad \text{Go to sten 3}. \end{split}$

- Go to step 3.

Otherwise (  $\overline{c}_j \ge 0 \ \forall j=1,...,n$  ): Termination. An optimal basic solution to the primal problem is found.

Business Computing and Operations Research WINFOR 337

### **Example – Revised Simplex Method**

Maximize  $(4 \ 2 \ 3) \cdot x$ 

$$\begin{pmatrix} 4 & 1 & 2 \\ 2 & 2 & 2 \end{pmatrix}$$
  $\cdot x \le \begin{pmatrix} 20 \\ 20 \end{pmatrix}$ ,  $x \ge 0 \Rightarrow$ 

$$\begin{pmatrix}
4 & 1 & 2 \\
3 & 3 & 3
\end{pmatrix} \cdot x \le \begin{pmatrix} 20 \\ 30 \end{pmatrix}, x \ge 0 \Rightarrow$$

$$A = \begin{pmatrix} 1 & 0 & 4 & 1 & 2 \\ 0 & 1 & 3 & 3 & 3 \end{pmatrix}, c = \begin{pmatrix} 0 & 0 & -4 & -2 & -3 \end{pmatrix}, b = \begin{pmatrix} 20 \\ 30 \end{pmatrix}$$

$$B(1) = 1, B(2) = 2 \Rightarrow Z = 0, \pi^{T} = \begin{pmatrix} 0 & 0 \end{pmatrix}, A_{B}^{-1} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, A_{B}^{-1} \cdot b = \overline{b} = \begin{pmatrix} 20 \\ 30 \end{pmatrix}$$

$$\overline{c}_3 = -4 - 0 = -4 \Rightarrow s = 3 \Rightarrow \lambda_0 = \min \left\{ \frac{20}{4}, \frac{30}{3} \right\} = 5 \Rightarrow r = 1$$

Business Computing and Operations Research WINFOR 338

### **Example – Revised Simplex Method**

$$\Rightarrow \lambda_0 = \min\left\{\frac{20}{4}, \frac{30}{3}\right\} = 5 \Rightarrow r = 1 \land B(1) = 3, B(2) = 2$$

Assuming 
$$\tilde{B}$$
 as the former basis, we get  $A_{\tilde{B}}^{-1} = P \cdot A_{\tilde{B}}^{-1} = \begin{bmatrix} e^1 & \dots & p & \dots & e^m \\ & & & & & \\ & & & & & \\ & & & & & \end{bmatrix} \cdot A_{\tilde{B}}^{-1}$ , with  $p = \begin{bmatrix} \dots & \dots & \dots & \dots & \dots & \dots \\ \frac{1}{a_{rs}} & \dots & \dots & \dots & \dots \end{bmatrix}$ 

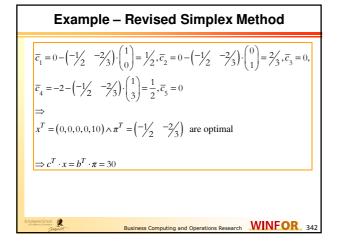

Thus, we have 
$$A_B^{-1} = \begin{pmatrix} \frac{1}{4} & 0 \\ -\frac{3}{4} & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} \frac{1}{4} & 0 \\ -\frac{3}{4} & 1 \end{pmatrix} \Rightarrow \overline{b} = \begin{pmatrix} \frac{1}{4} & 0 \\ -\frac{3}{4} & 1 \end{pmatrix}, b = \begin{pmatrix} \frac{1}{4} & 0 \\ -\frac{3}{4} & 1 \end{pmatrix} \begin{pmatrix} 20 \\ 30 \end{pmatrix} = \begin{pmatrix} 5 \\ 15 \end{pmatrix}$$

$$\Rightarrow \pi^T = c_B^T \cdot A_B^{-1} = \begin{pmatrix} -4 & 0 \end{pmatrix} \cdot \begin{pmatrix} \frac{1}{4} & 0 \\ 3 & 1 \end{pmatrix} = \begin{pmatrix} -1 & 0 \end{pmatrix}$$

### Example – Revised Simplex Method $\vec{\xi}_1 = 0 - (-1 \quad 0) \cdot \begin{pmatrix} 1 \\ 0 \end{pmatrix} = 1, \vec{\xi}_2 = \vec{\xi}_3 = 0, \vec{\xi}_4 = -2 - (-1 \quad 0) \cdot \begin{pmatrix} 1 \\ 3 \end{pmatrix} = -1, \vec{\xi}_3 = -3 - (-1 \quad 0) \cdot \begin{pmatrix} 2 \\ 3 \end{pmatrix} = -1 \Rightarrow s = 4$ $\Rightarrow \vec{a}^4 = A_B^{-1} \cdot a^4 = \begin{pmatrix} 1/4 & 0 \\ -2/4 & 1 \end{pmatrix} \cdot \begin{pmatrix} 1 \\ 3 \end{pmatrix} = \begin{pmatrix} 1/4 \\ 2/4 \end{pmatrix} \Rightarrow \lambda_0 = \min \left\{ \frac{5}{12} \cdot \frac{15}{12} \right\} = \frac{60}{9} = \frac{20}{3}$ Thus, we have $A_B^{-1} = \begin{pmatrix} 1 & -\frac{1}{9} \\ 0 & \frac{4}{9} \end{pmatrix} \cdot \begin{pmatrix} \frac{1}{4} & 0 \\ 0 & \frac{4}{3} & 1 \end{pmatrix} = \begin{pmatrix} \frac{12}{36} & -\frac{1}{9} \\ -\frac{13}{3} & \frac{4}{9} \end{pmatrix} = \begin{pmatrix} \frac{1}{3} & -\frac{1}{9} \\ -\frac{1}{3} & \frac{4}{9} \end{pmatrix}$ $\vec{x} = (-\frac{1}{3} \cdot \frac{1}{9}) \cdot b = \begin{pmatrix} \frac{1}{3} & -\frac{1}{9} \\ -\frac{1}{3} & \frac{4}{9} \end{pmatrix} \cdot \begin{pmatrix} 20 \\ 30 \end{pmatrix} = \begin{pmatrix} 10/3 \\ 20/3 \end{pmatrix},$ $\vec{x} = (-\frac{7}{6}, \frac{1}{3} \cdot \frac{1}{9}) = (-4 - 2) \cdot \begin{pmatrix} \frac{1}{3} & -\frac{1}{9} \\ -\frac{1}{3} & \frac{4}{9} \end{pmatrix} = \begin{pmatrix} -\frac{7}{2} & -\frac{4}{6} \end{pmatrix}$

### Example — Revised Simplex Method $\overline{c}_1 = 0 - \left(-\frac{2}{3}, -\frac{4}{9}\right) \cdot \binom{1}{0} = \frac{2}{3}, \overline{c}_2 = 0 - \left(-\frac{2}{3}, -\frac{4}{9}\right) \cdot \binom{0}{1} = \frac{4}{9}, \overline{c}_3 = 0, \overline{c}_4 = 0, \\ \overline{c}_5 = -3 - \left(-\frac{2}{3}, -\frac{4}{9}\right) \cdot \binom{2}{3} = -\frac{1}{3} \Rightarrow s = 5$ $\Rightarrow \overline{a}^5 = A_B^{-1} \cdot a^5 = \begin{pmatrix} \frac{1}{3}, -\frac{1}{3} \\ -\frac{1}{3}, \frac{4}{9} \end{pmatrix} \cdot \binom{2}{3} = \begin{pmatrix} \frac{1}{3} \\ \frac{1}{3} \end{pmatrix} \Rightarrow \lambda_0 = \min \left\{ \frac{10}{3}, \frac{20}{3} \\ \frac{1}{3}, \frac{20}{3} \\ \frac{1}{3}, \frac{20}{3} \\ \frac{1}{3} \end{pmatrix} = 10$ $\Rightarrow r = 2 \Rightarrow B(1) = 3, B(2) = 5 \Rightarrow$ Thus, we have $A_B^{-1} = \begin{pmatrix} 1 & -\frac{1}{2} \\ 0 & \frac{3}{2} \end{pmatrix} \cdot \begin{pmatrix} \frac{1}{3} & -\frac{1}{9} \\ -\frac{1}{3} & \frac{4}{9} \end{pmatrix} = \begin{pmatrix} \frac{1}{2} & -\frac{1}{3} \\ -\frac{1}{2} & \frac{2}{3} \end{pmatrix}$ $\overline{b} = \begin{pmatrix} \frac{1}{2} & -\frac{1}{3} \\ -\frac{1}{2} & \frac{2}{3} \end{pmatrix}, b = \begin{pmatrix} \frac{1}{2} & -\frac{1}{3} \\ -\frac{1}{2} & \frac{2}{3} \end{pmatrix} \cdot \begin{pmatrix} 20 \\ 30 \end{pmatrix} = \begin{pmatrix} 0 \\ 10 \end{pmatrix}, \pi^T = c_B^T \cdot \begin{pmatrix} \frac{1}{2} & -\frac{1}{3} \\ -\frac{1}{2} & \frac{2}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{2} & \frac{2}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{2} & \frac{2}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{2} & \frac{2}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{2} & \frac{2}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{2} & \frac{2}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{2} & \frac{2}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{2} & \frac{2}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{2} & \frac{2}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{2} & \frac{2}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{2} & \frac{2}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{2} & \frac{2}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{2} & \frac{2}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{3} & \frac{2}{3} & -\frac{1}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{3} & -\frac{1}{3} & -\frac{1}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{3} & -\frac{1}{3} & -\frac{1}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{3} & -\frac{1}{3} & -\frac{1}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{3} & -\frac{1}{3} & -\frac{1}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{3} & -\frac{1}{3} & -\frac{1}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{3} & -\frac{1}{3} & -\frac{1}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{3} & -\frac{1}{3} & -\frac{1}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{3} & -\frac{1}{3} & -\frac{1}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{3} & -\frac{1}{3} & -\frac{1}{3} \end{pmatrix} = \begin{pmatrix} -\frac{1}{3} & -\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{3} & -\frac{1}{3} & -\frac{1}{3} & -\frac{1}{3$

### 3.2 Analyzing the complexity

- Clearly, at first glance, you would assume that the main complexity effect of the revised simplex algorithm is from the fact that it's application reduces the values to be updated from an (m+1)x(n+1) tableau to a (m+1)x(m+1)
- However, we have to generate the reduced costs by iteratively computing  $\pi^T A_i$  for a considered non-basic column. Thus, if we have to do this for all these non-basic columns this requires  $m \cdot (n-m)$  multiplications
- But this is not significantly less than the number of multiplications needed to update the tableau in the ordinary simplex method!

humpeter	School	13
of Brazzania stro	LOXING	

Business Computing and Operations Research WINFOR 343

### Positive effect of the revised simplex

- The practical complexity reducing effect of the revised simplex are somewhat more subtle but significant nonetheless
- First, it is quite likely that we need not compute the relative costs of every non-basic column if we (for instance) always take the first column with negative costs (improving alternative) (e.g. rule of Bland)
  - This significantly reduces on the average the computational effort to some fraction
  - This fraction is determined by the average number of columns that must be examined until one with negative relative cost is identified

Business Computing and Operations Research WINFOR 344

### Positive effect of the revised simplex

- Second, each pricing operation (i.e., the calculation of the reduced cost value  $\pi^T A_i$  for a considered column j) uses the column  $A_i$  of the original Tableau
- We will see in many practical applications in Combinatorial Optimization these matrices are often very sparse (many zero entries)
  - Thus, the necessary prizing computations can be performed very
  - Moreover, the original matrix can be stored in a very compact way

### 

### Update at any stage /

 By using the current vector η, we can efficiently generate all matrices P<sub>l</sub> and generate

 $CARRY^{(l)} = P_l \cdot P_{l-1} \cdot \dots \cdot P_1 \cdot CARRY^{(0)}$ 

- Moreover, due to the current vector  $\eta$ , the matrix  $P_l$  can be stored very efficiently
- However, if the sequence of η becomes too long, it can be replaced by a shorter sequence
  - This replacement process is denoted as reinversion
  - It generates an equivalent but shorter sequence of pivots to attain the current basis
  - Such techniques can greatly reduce the storage and time required to perform the simplex algorithm, especially if special attention is paid to reducing the number of nonzero elements in the  $\eta$ -sequence (see Orchard-Hays (1968) or Lasdon (1970)).

### 3.3 Solving the Max Flow Problem

- In anticipation of the applications that are considered in the Sections 6 and 7 where we introduce and consider the Shortest Path Problem and the Max Flow Problem, in what follows, we show an interesting application of the revised simplex procedure
- Both applications are network problems that can be formulated as Linear Programs and the constraint matrix can be derived directly from the graph underlying the problem

numpeter School  A busine ac Domesio  (2004-45)	Business Computing and Operations Research	WINFOR

# The Max Flow Problem 3.3.1 Definition Given a flow network N = (s, t, V, E, b) with n = |V| nodes and m = |E| arcs, an instance of the Max Flow Problem (MFP) is defined as the optimization problem of finding a flow $f \in IR^m$ on each edge with maximal value v from the single source node s to the single terminal node t. On each edge, this flow has to be lower or equal to the capacity vector $b \in IR^m$ . Business Computing and Operations Research WINFOR 349

### We now formulate this problem as an LP in a somewhat surprising way Since the arcs are numbered by e<sub>1</sub>,...,e<sub>m</sub>, we introduce C<sub>1</sub>,...,C<sub>p</sub> as a complete enumeration of every chain (i.e., path) from s to t As known from the revised simplex algorithm introduced above, the theoretical Linear Program covers m rows and p columns but the considered LP in each step will comprise only m columns

Specific problem definition

## Arc-chain incidence matrix $D=[d_{i,j}]$ • In order to unambiguously define possible paths, we determine the so-called arc-chain incidence matrix as follows: $\forall i \in \{1,...,m\} : \forall j \in \{1,...,p\} : d_{i,j} = \begin{cases} 1 & \text{if } e_i \in C_j \\ 0 & \text{otherwise} \end{cases}$ • The capacity constraints are given by: $D \cdot f \leq b$ • The objective function pursues the maximization of all the flows in all defined chains, i.e., $\min c^T \cdot f$ • with $c = (-1, \dots, -1)$ • Business Computing and Operations Research WINFOR 351

### **Complete Linear program**

• Thus, we obtain the following LP

$$\min c^{\mathsf{T}} \cdot f$$
  
s.t.  $D \cdot f \le b \land f \ge 0$ 

By introducing a slack vector  $s \in IR^m$ , we transform this LP into standard form and extend the respective vectors as follows

Flow vector: 
$$\hat{f} = (f|s)$$
, cost vector  $\hat{c} = (f|0)$ , and  $\hat{D} = (D|E^m)$ 

This leads to the LP

min 
$$z=\hat{c}^T \cdot \hat{f}$$
  
s.t.  $\hat{D} \cdot \hat{f} = b \wedge \hat{f} \ge 0 \Rightarrow f \ge 0$ 

Business Computing and Operations Research WINFOR 352

### Consequences

- Clearly, each slack variable s<sub>i</sub> represents the difference between the flow in arc i and the capacity  $b_i$ , with i=1,...,m
- We now apply the revised simplex algorithm
  - Fortunately, we do not have to apply the two-phase method since this problem is solvable with the trivial solution f = 0, s = b that represents the zero flow
  - The criterion for a new column to enter the basis are negative reduced costs, given by

$$\overline{c}_j = c_j - \pi^{\mathsf{T}} \cdot D_j < 0 \underset{\mathsf{Since} \ c_j = -1}{\Longleftrightarrow} -1 - \pi^{\mathsf{T}} \cdot D_j < 0 \Longleftrightarrow -\pi^{\mathsf{T}} \cdot D_j < 1$$

• D<sub>i</sub> is the jth column of the arc-chain incidence matrix D

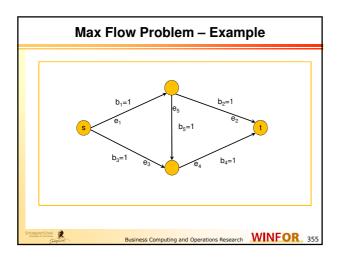

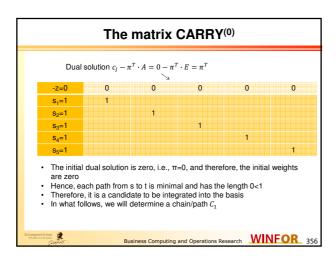

Business Computing and Operations Research WINFOR 353

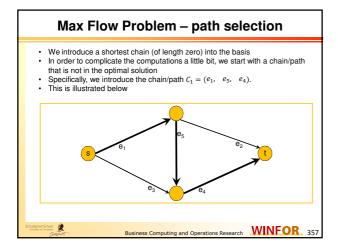

### Consequences

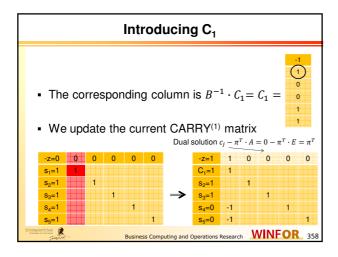

- Clearly,  $-\pi^T \cdot D_i$  is the cost of the chain/path  $C_i$ under the weight vector  $-\pi$
- In order to find a profitable column, we need to find the *shortest chain* from *s* to *t* under the weight vector  $-\pi$  that weights less than 1
  - If that shortest chain/path, say C<sub>i</sub>, has cost no less than 1, then the optimality criterion is satisfied
  - If not, we introduce  $C_i$  into the basis
- The calculation therefore requires only the maintenance of an (m+1)x(m+1) CARRY matrix and the repeated solution of the shortest-path problem

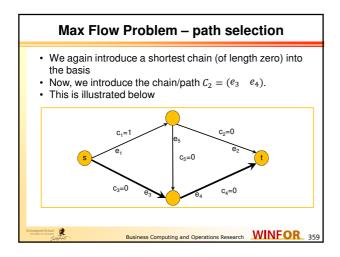

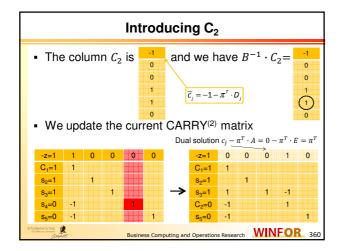

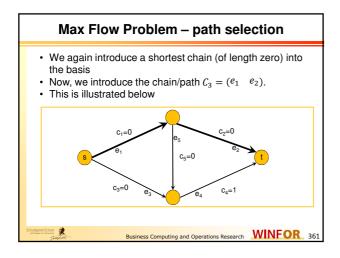

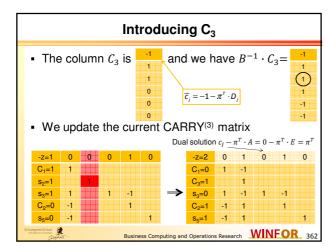

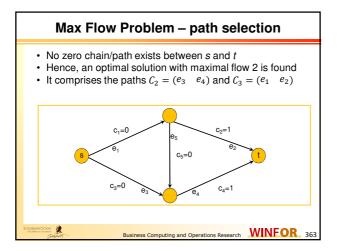

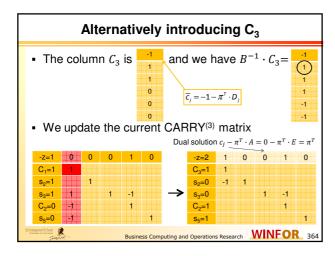

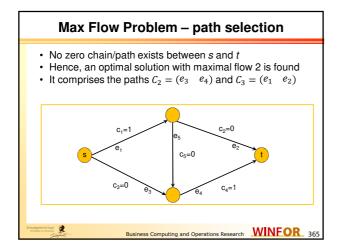

### 3.4 The Dantzig-Wolfe Decomposition It often happens that a large linear program is actually a collection of smaller linear programs that are largely independent of each other Therefore, the revised simplex algorithm allows us to decompose the entire problem into smaller master- and subproblems The "communication" between these problems can be directly derived from the revised simplex Thanks to this decomposition, problems that may become too large to be solved efficiently (e.g., due to space requirements) can be solved very fast Business Computing and Operations Research WINEOR 366

### • We analyze the entire LP with two subproblems • This leads to the following scheme of a matrix • This leads to the following scheme of a matri

Business Computing and Operations Research WINFOR 367

### The complete LP $\min z = c^T \cdot x + d^T \cdot y$ s.t. $D \cdot x + F \cdot y = b_0$ $A \cdot x = b_1$ $B \cdot y = o_2$ $x, y \ge 0$ We denote the $m_0$ equations the coupling equations The succeeding sets of rows are the subproblems A and B

### The subproblem A• We consider the constraints of subproblem A, i.e., $A \cdot x = b_1 \\ x \ge 0$ • By Theorem 1.3.19, we know that any feasible point in this subproblem can be written as a convex combination of edge points. We denote these points as $x_1, ..., x_p$ , with $x = \sum_{j=1}^p \lambda_j \cdot x_j \text{ where } \forall j \in \{1,...,p\} : \lambda_j \ge 0 \text{ and } \sum_{j=1}^p \lambda_j = 1$

### Analogously: The subproblem B

• We consider the constraints of subproblem B, i.e.,

$$B \cdot y = o_2$$
$$y \ge 0$$

By Theorem 1.3.19, we know that any feasible point in this subproblem can be written as a convex combination of edge points. We denote these points as  $y_1, \dots, y_q$ , with

$$y = \sum_{j=1}^{q} \mu_j \cdot y_j$$
 where  $\forall j \in \{1,...,q\} : \mu_j \ge 0$  and  $\sum_{j=1}^{q} \mu_j = 1$ 

Business Computing and Operations Research WINFOR 370

### Modified structure of the LP

- We replace x and y by their derived representations
- This leads to the following modified scheme (in what follows, denoted as the master problem)

ables		
$\mu_1,,\mu_q$	Right hand side	Dimensions
$Fy_1,,Fy_q$	b <sub>0</sub>	m <sub>o</sub> rows
0,,0	1	1 row
1,,1	1	1 row
	$\mu_1,,\mu_q$ $Fy_1,,Fy_q$ $0,,0$	$\mu_1,,\mu_q$ Right hand side $Fy_1,,Fy_q$ $b_0$ $0,,0$ 1

Costs

$$\min z = \sum_{j=1}^{p} \lambda_{j} \cdot c^{\mathsf{T}} \cdot x_{j} + \sum_{j=1}^{q} \mu_{j} \cdot d^{\mathsf{T}} \cdot y_{j}$$
while  $\lambda, \mu \geq 0$  are the new variables  $\lambda \in \mathit{IR}^{p} \wedge \mu \in \mathit{IR}^{q}$ 

Business Computing and Operations Research WINFOR 371

### Consequences

- Due to the transformation, we may obtain an astronomical number of columns, one for each vertex of each of the two subproblems
- However, the number of rows is significantly reduced from  $m_0 + m_1 + m_2$  to  $m_0 + 2$
- Furthermore, the revised simplex method can be applied with a CARRY matrix of size  $(m_0 + 3) \times (m_0 + 3)$
- · Hence, much larger instances may fit into fast-access storage
  - Size of CARRY:  $(m_0+3)\times(m_0+3)$  instead of  $(m_0+m_1+m_2+1)$  $1)\times (m_0+m_1+m_2+1)$
  - If, for instance, it holds that  $m_0 = m_1 = m_2 = m$ , we have  $(m+3)^2$ instead of  $(3 \cdot m + 1)^2$ , i.e., almost a factor of  $3^2 = 9$

humpeter	School Extensio	2
	12	0448

### Applying the revised simplex

- In the first row, we have the prices (reduced costs)
- This is a partitioned vector  $(\pi, \alpha, \beta)$  where  $\pi \in$  $IR^{m_0}$  corresponds to the first  $m_0$  rows and  $\alpha, \beta \in IR$  to the next two rows of the master problem, respectively
- The reduced costs of the  $\lambda_i$ -column are given by

$$\overline{c}_{j} = c^{\mathsf{T}} \cdot x_{j} - (\pi, \alpha, \beta) \cdot \begin{bmatrix} D \cdot x_{j} \\ 1 \\ 0 \end{bmatrix} = c^{\mathsf{T}} \cdot x_{j} - \pi^{\mathsf{T}} \cdot D \cdot x_{j} - \alpha$$

• Hence, the criterion for a column to be brought into the current basis is

$$c^{\mathsf{T}} \cdot x_j - \pi^{\mathsf{T}} \cdot D \cdot x_j - \alpha < 0 \Leftrightarrow c^{\mathsf{T}} \cdot x_j - \pi^{\mathsf{T}} \cdot D \cdot x_j < \alpha$$
Business Computing and Operations Research WINFOR 373

### Pricing problem A

- If  $c^T \cdot x_i \pi^T \cdot D \cdot x_i < \alpha$  holds for any vertex of Subproblem A, we have found a profitable column among the first p columns
- However, since an exhaustive exploration of the total number of possible columns (i.e., for each possible vertex of Subproblem A) would be impractical, we pursue the finding of the optimal vertex of the following LP

$$\mathsf{min}_{\mathsf{all \, vertices \, } \mathsf{x}_j \, \mathsf{of \, Subprobelm \, A}} \, \, \mathsf{c}^\mathsf{T} \cdot \mathsf{x}_j - \pi^\mathsf{T} \cdot \mathsf{D} \cdot \mathsf{x}_j = \left( \mathsf{c}^\mathsf{T} - \pi^\mathsf{T} \cdot \mathsf{D} \right) \cdot \mathsf{x}_j$$

• Thus, the pricing problem is

$$\min \left(c^{T} - \pi^{T} \cdot D\right) \cdot x$$
  
s.t.  $A \cdot x = b_{1} \land x \ge 0$ 

Business Computing and Operations Research WINFOR 374

### Pricing problem A

- If the objective function value of the optimal solution is lower than  $\alpha$  the resulting column can be introduced into the basis
  - Hence, the master problem integrates the new column into the basis and, therefore, updates the current solution
  - The newly attained solution results in a new price vector sent to subproblem A
- Otherwise, no further improvement is possible and the solution of the master problem is kept unchanged according to the input of Subproblem A

### Pricing problem B

• Similarly, we can determine if there is a favorable column among the last q columns by solving

min 
$$(d^T - \pi^T \cdot F) \cdot y$$
  
s.t.  $B \cdot y = b_2 \land y \ge 0$ 

• and comparing the attained minimum cost to  $\beta$ , by an argument analogous to that surrounding the pricing problem A

Business Computing and Operations Research WINFOR 376

### **Procedure decomposition**

```
opt := 'no'
set up CARRY with zero row (\pi, \alpha, \beta);
while opt = 'no' do
begin solve the LP
      \min \ (c^T - \pi^T D) \cdot x = z_0 \text{ s. t. } Ax = b_1, x \geq 0
      \text{if } Z_0 < \alpha
           \mbox{\it then} generate the column corresponding to the solution with this cost, and pivot in CARRY
            else begin solve the LP
                         \min (d^T - \pi^T F) \cdot y = z_0 \text{ s.t. } By = b_2, y \ge 0
                         \text{if } Z_0 < \beta
                                     then generate the column corresponding to the solution with this cost, and pivot in CARRY
                                      else opt := 'yes'
            end
```

### **Summary**

We verbally sum up the operations of the decomposition method:

- After being solved, the master problem, based on its overall view of the entire situation, sends a price to subproblem A
- This subproblem A then responds with a solution (a proposal) for possibly improving the overall problem, based on its local information and the price
- The master problem then weighs the cost  $(Z_0)$  of this proposal against its criterion  $\alpha$  for subproblem A
  - If the proposal is cheaper than  $\alpha$ , it is implemented by bringing it into the basis. This results in an update of the current solution (and prices)
  - If not, subproblem B is sent a price vector and asked for a proposal.
- As long as a subproblem can produce a favorable proposal, the master problem can find a favorable pivot
- When neither subproblem can come up with a favorable proposal, we have reached an optimal solution of the entire problem

### An illustrative example A little arithmetic shows the effectiveness of the approach in size reduction of the mapped problems Suppose we have 100 subproblems, each with 100 rows, and 100 coupling equations. Then the original problem has 10,100 rows • CARRY has 10,101 x 10,101 entries, i.e., approximately 108 entries. May be too many for the working memory of a computer • The master problem has a CARRY with 201 x 201 entries. These are approximately 4 x 104 entries, which is practical to store in the fast memory of any reasonably large computer All in all, the clear advantage of the decomposition algorithm is its

### Business Computing and Operations Research WINFOR 380

Note that it cannot be said much about the time requirements, because we do not know how many times the subproblems must be

effect on the space requirements

solved before optimality is reached
