#### **4** Scheduling

- In this section, we consider so-called "Scheduling problems"
- I.e., if there are altogether M machines or resources for each machine, a production sequence of all N jobs has to be found as well as the determination of the time tables

Business Computing and Operations Research WINFOR 347

Business Computing and Operations Research WINFOR 348

- Consequently, we have to decide on • The sequence of the respective jobs on each machine
  - and its time table

2

Outline of the chapter 1. Preliminaries 1. Mathematical model 2. Objective functions 2. Single Machine Models 3. Sequencing problem with heads and tails 4. Multiple stages Use of priority rules
 Elaborated heuristics The Shifting Bottleneck Procedure
 Tabu Search by Nowicki-Smutnicki 5. Flow-shop problems 1. The procedure of Johnson 2. The multiple-stage case 

#### 4.1 Preliminaries

- Production program is given
- Lot sizes are given .
- Process sequence of each job is given
- Operating times are given
- No operation can be processed simultaneously on more than one machine
- At each point of time every machine can process at most one job
- At the beginning of the planning horizon all *N* jobs and their data are available (static problem)
- Transports and storage are never bottlenecks .
- . No maintenance and repair activities
- On each machine setup times are independent of the realized operation sequence

- In case of the job sequence restrictions, the formulation depends on the structure of the found solution
- But, we have to ensure that there is no simultaneous processing of two jobs on any machine, wherefore an arbitrary sequence of those jobs has to be realized

Therefore, there are altogether two possible cases:

First case (n before k):

#### (1) $t_{m,n} + p_{m,n} \le t_{m,k}$ Second case (*k* before *n*):

(2)  $t_{m,k} + p_{m,k} \le t_{m,n}$ 

2

⇒ Both possibilities have to be considered in the model!

#### 4.1.2 Objective functions

- The model defined above can be regarded as a general starting point for so-called job-shop scheduling problems
- It abstains from the definition of a particular objective function but can be extended by a specific application-dependent one
- A huge set of different objective functions is proposed in literature. These functions mainly influence the efficiency of applied solution procedures
- In the following, we will give some examples of well-known objectives

Business Computing and Operations Research WINFOR 356

2

Minimization of cycle time • Here, we consider the duration of producing the total production quantities  $Minimize Z_{i} = t_{max} = max \{C_{[M],n} | n \in \{1,...,N\}\}$ with:  $\forall n \in \{1,...,N\}: C_{[M],n}:$ Point of time where the last processing of job *n* is finalized WINER 257

Business Computing and Operations Research WINFOR 359

2

<section-header><list-item><list-item><list-item><list-item><list-item><list-item>

Minimization of total lateness (or tardiness) - Here, we want to minimize the total lateness over all N jobs to be produced in the considered production system - Consequently, there is no longer compensation between early and late deliveries possible Minimize  $Z_6 = \sum_{n=1}^{N} \max\{C_{[M],n} - d_n, 0\}$ with :  $d_n$ : Due date of job n2 

#### 4.1.3 Schedule classes

- In the following, we introduce some basic terms for specific types of schedules
- In scheduling, a distinction is frequently made between
  - Sequence,Schedule and
- Scheduling policy Sequence
- Corresponds to a specific permutation of jobs to be processed on a given machine Schedule

- Schedule Usually corresponds to an allocation of jobs within a more complicated setting of machines, which could allow for preemptions of jobs by other jobs that are released at later points in time. Comprises time tables Scheduling policy Often used in stochastic settings; a policy prescribes an appropriate action for any of the states the system may be in. In deterministic cases, usually only sequences or schedules are of importance but can be extended by rule definitions 2
  - WINFOR 365 ss Computing and Operations Research

#### **Active schedules**

#### 4.1.3.2 Definition

2

A feasible schedule is called active if no operation can be completed earlier by starting earlier or changing the process sequence on machines without delaying any other operation

#### Proof of the lemma

- · Let us assume there is a non-delay schedule that is not active
- Then, we know there is a machine where shifting an operation i into an earlier position at point of time t results in an earlier completion without delaying the other . operations
- But, if this is true, we know that during the processing of the schedule on machine m there is a constellation at point of time t where the considered machine is idle but can process job i instead This is a contradiction to the assumption that the schedule .
- is non-delay

2

### Semi-active schedules

#### 4.1.3.4 Definition

.

A feasible schedule is called semi-active if no operation can be completed earlier without altering the processing sequence on any of the machines

Business Computing and Operations Research WINEOR 371

<section-header><section-header><section-header><section-header><section-header><section-header><section-header><text><text>

#### 4.2 Single-Stage Systems

- Now, we consider a single production stage only
- i.e., M=1, wherefore we have only one indexed processing times p<sub>1</sub>,...,p<sub>N</sub>
- Now, the complexity of the models only depends on the considered objective function
- There are some constellations that can be optimally solved in  $O(N \log N)$  time using a simple priority rule as well as models that are already *NP*-complete problems. And both happens despite the fact that besides their objective function, both problems are completely the same one-stage problems

#### Minimization of cycle time

Trivial problem

2

2

- Each solution leads to the same result
- Therefore, an arbitrary solution is already an optimal one

#### **Proof of Theorem**

- We will show the claim by contradiction

2

- Therefore, we assume that there is an optimal sequence of the problem that does not fulfill all the restrictions of the WSPT policy
- Consequently, there are two adjacent jobs, say job *j* followed by job *k*, such that

 $w_i/p_i < w_k/p_k$ 

Business Computing and Operations Research \_378

#### **Proof of Theorem**

- Assume job j starts its processing at time t
- Let us perform an interchange of *j* and *k*
- Therefore, the modified schedule starts job *k* now at *t* while **all other jobs remain in their original position**
- Consequently, their weighted objective value is not affected at all and, therefore, remains unchanged
- Call the old schedule S and the new modified one T

### **Proof of Theorem**

• Under schedule *S*, the total weighted completion of jobs *j* and *k* is rated by:

$$(t + p_j) \cdot w_j + (t + p_j + p_k) \cdot w_k$$

• Under schedule *T*, the total weighted completion of jobs *j* and *k* is rated by:

$$(t+p_k)\cdot w_k + (t+p_j+p_k)\cdot w_j$$

.

2

Business Computing and Operations Research

# Proof of Theorem V

Consequently, solution T is better and, therefore, the proof is completed

# **Proof of the Corollary**

- To prove the corollary, we may use again Theorem 4.2.1
- To do so, we easily derive that the objective function for minimizing the total lead time Z<sub>3</sub> is a special case of the more general weighted sum of lead time Z<sub>8</sub>
- In this case all weights are set to 1

2

- By applying Theorem 4.2.1, we can derive that we receive the optimal sequence by using the WSPT-policy, i.e., by respecting this special setting, we sort all jobs in nonincreasing sequence of the w/p<sub>j</sub>=1/p<sub>j</sub>values
- Consequently, the jobs are sorted in an non-decreasing sequence of the p<sub>j</sub>-values as defined by the well-known SPT-rule. This completes the proof of the corollary

Business Computing and Operations Research WINFOR 384

#### **Precedence constraints**

- How is the result affected by precedence constraints?
- In the following, we introduce additional precedence constraints limiting the solution space through the exclusion of some possible solutions. These constraints are very simple and can be described through parallel chains defining which job has to be processed before another one
- This is a situation that frequently occurs during the processing of multi-stage systems
- First, we can process only entire chains. To solve these problems optimally, we can use the following extended Theorem 4.2.3

#### **Proof of the Theorem**

- Again, we show the claim by contradiction

2

- Therefore, we assume there is an optimal production plan violating the rule definition .
- Therefore, there are **two neighbored chains** (1,...,k) and (k+1,...,l) where the defined priority rule is not fulfilled Again, we can derive that there is no impact on the weighted lead time of the jobs not belonging to one of the two chains
- Moreover, we derive **schedule** *T* from the **current schedule denoted** *S* through the exchange of the two neighboring chains, i.e., in *T* we process (*k*+1,...,*l*) before (1,...,*k*) is processed .
- In what follows, we compute the respective objective values of the both chains for the two possible constellations S and T

#### Consequence

The objective value of schedule T is better than the result under schedule S and, therefore, the optimality of the rule defined above is shown

Business Computing and Operations Research WINFOR 392

> This completes the proof

2

#### Allowing preemption

- Assume now that the scheduler has the freedom to process any number of jobs in a chain (while adhering to the precedence constraints) without necessarily having to complete all the jobs in the chain before switching to another chain
- In what follows, we consider again the case of multiple chains
- Moreover, total weighted lead time is assumed to be the objective function
- Then, we may apply the result given in the following Theorem 4.2.5 in order to derive an optimal production plan

2

#### Subchain preemption

#### 4.2.5 Lemma

2

2

If job I\* is the p-factor of the chain (1,...,k), then there exists an optimal sequence that processes jobs 1,...,I\* one after another without interruption by jobs from other chains

Business Computing and Operations Research WINFOR 395

#### **Proof of the Theorem**

- Again, we prove this claim by contradiction
- Suppose that under the optimal sequence, the processing of the subsequence 1,...,/\* is interrupted by a job, say job v, from another chain that has to be processed simultaneously
- Thus, the optimal sequence contains the subsequence 1,...,u,v,u+1,...,k, say subsequence S
- It suffices to show that either with subsequence v,1,...,/\*, say S' or with 1,...,/\*, v, say S'', the total weighted completion time is less than with subsequence S
- We know that the lead time of all other jobs besides 1,...,*I*<sup>\*</sup> and *v* is independent of the chosen subsequence *S*, *S*<sup>\*</sup>, and *S*<sup>\*</sup>

Business Computing and Operations Research WINFOR 396

- In the following, we therefore assume  $S\!\!>\!\!S$  as well as  $S'\!\!>\!\!S$ 

# Case 1: S'>S • S=(1,...,u,v,u+1,...,l^\*); S'=(v,1,...,u,u+1,...,l^\*) Since C is better than C

• Since *S* is better than *S*', we can apply the proof of Theorem 4.2.3 to derive that it holds:

$$\frac{w_{v}}{p_{v}} < \frac{w_{1} + \dots + w_{u}}{p_{1} + \dots + p_{u}}$$

- If this is not true, we do not worsen the solution by applying the proof of Theorem 4.2.3 and process v before the job sequence 1,...,u
- It is trivial that we can choose S' instead of S if it holds  $S' {\leq} S$

#### Using the result

- The result derived above is intuitive. Its condition implies that the ratios of the total weight divided by the total processing time of the jobs in the string 1,...,/\* must be decreasing in some sense
- If one had decided to start processing a stream, it makes sense to proceed until job /\* is obtained
- By simultaneously using the result derived above, we can use the following algorithm for solving our problem optimally

Business Computing and Operations Research WINFOR 401

Solution procedure
4.2.6 Algorithm
Whenever the machine is freed, select among the remaining chains the one with the highest p- factor and process this chain without interruption up to the job that determines its p-factor. Note that this includes this job itself.
Schumpeter School Business Computing and Operations Research WINFOR 402

Example	Э
---------	---

- Consider the following two chains
  - 1 2 3 4
  - 5 6 7

2

• The weights and processing times of the jobs are given below

	Jobs	1	2	3	4	5	6	7
	Weight	6	18	12	8	8	17	18
	Processing time	3	6	6	5	4	8	10
tumpeter Sci A Balins ec Dor	thaal	В	usiness Cor	nputing and	Operations	Research	WINF	OR 403

- The  $\rho$ -factor of the first chain is (6+18)/(3+6)=24/9 and determined by job 2
- The *p*-factor of the second chain is (8+17)/(4+8)=25/12 and determined by job 6
- Therefore, we start processing the first chain (Schedule: 1 2)
- The ρ-factor of the remaining first chain is (12)/(6)=2 and determined by job 3
  Therefore, we proceed with the second chain (Schedule: 1 2 5 6)
- The  $\rho$ -factor of the remaining second chain is (18)/(10)=1.8 and determined by job 7
- Hence, we proceed with the first chain (Schedule: 1 2 5 6 3) • The *p*-factor of the remaining first chain is (8)/(5) and determined by job
- <sup>4</sup> Consequently, we proceed with the second chain (Schedule: 1 2 5 6 3 7)

Resulting schedule is 1 - 2 - 5 - 6 - 3 - 7 - 4

Business Computing and Operations Research

2

#### **Proof of the Theorem**

- In order to complete the proof, we move the sequence position of job  $j^*$  just behind job  $j^{**}$ . What are the consequences for the objective value of the solution?
  - All jobs that are located between j\* and j\*\* in the old schedule S are processed earlier, wherefore the objective function value is not negatively affected
    What about job j\*? This is the only job whose completion time is increased through the applied modification
    But we know by assumption that this modified value leads to a smaller penalty function value than the one caused by j\* in schedule S

  - Finally, we can state that the value for  $j^{**}$  in the new schedule is not increased. Therefore, the maximum of all lateness values in the new schedule is not larger than the objective value of S

Business Computing and Operations Research WINFOR 410

· This completes the proof

2

Special case Z<sub>7</sub> 4.2.9 Corollary For the special case  $h_i = max\{0, C_i - d_i\}$ , the application of rule EDD (Earliest Due Date), which schedules the different jobs in a nondecreasing sequence of due dates, results in the optimal solution. Business Computing and Operations Research WINFOR 411

# **Proof of the Corollary**

- In order to prove the claim of the corollary, we can apply Theorem 4.2.8 and Algorithm 4.2.7 Hence, iobs are scheduled in the first iterations
- and, therefore, at the end of the arising total sequence with the lowest penalty value
- These values only depend on individual due dates and, therefore, lead to a situation where jobs with the highest due dates are preferred (at the end of the schedule!)
- By preferring the highest due dates for an inverted sequence, we apply the EDD-rule for the original one

2

#### **Total lateness**

- This problem is proven to be NP-hard in the ordinary sense, i.e., it exists a pseudo-polynomial time algorithm based on dynamic programming
- However, this problem can be simplified by scheduling jobs which are non-time-critical at the end, i.e., the total processing time of all jobs is lower or equal to their due date

Business Computing and Operations Research WINFOR 413

Business Computing and Operations Research WINFOR 414

2

# 4.3 Sequencing problem with heads and tails In what follows, we take a step towards multiple stage problems Therefore, we consider a single stage where a scheduling sequence has to be determined. However, each job has preceding and subsequent processes at other stages, which are defined as head and tails Consequently, beside *p<sub>i</sub>* the processing time of the *i*-th job at the considered stage, there is a head *a*<sub>i</sub> and a tail *q<sub>i</sub>*

 As the pursued objective we consider the minimization of the makespan (lead time)

#### **Proof of the Lemma**

- Consider an arbitrary set of jobs *I*
- At least *a*<sub>min,/</sub> time units have to elapse before the processing can start
- This processing takes altogether additional p<sub>total,</sub>/ time units
- Finally, there is always one job processed at the last position at the considered stage whose tail increases the total makespan of the processing. And this tail is larger than or equal to  $q_{\min,l}$
- Thus, we have shown that the defined sum is a lower bound for the cycle time

Business Computing and Operations Research WINFOR 416

- This obviously completes the proof

2

<section-header><section-header><section-header><section-header><text><text><text><page-footer>

#### Starting point: The Schrage algorithm

In this greedy approach, we always schedule the ready job with the greatest tail

- (*i*) Set  $t = \min_{i \in I} a_i; U = \emptyset; \overline{U} = \{1, \dots, n\};$
- (*ii*) At time t, schedule amongst the ready jobs *i*
- $(a_i \le t)$  of  $\overline{U}$ , job *j* with  $q_j = \max\{q_i \mid i \in \overline{U} \land a_i \le t\}$ (or any one in the case of ties)
- (iii) Set:  $U = U \cup \{j\}; \overline{U} = \overline{U} \setminus \{j\}; t_i = t;$
- $t = \max\left\{t_j + p_j, \min_{i \in \overline{U}} a_i\right\};$
- If U is equal to  $I = \{1, ..., n\}$ , the algorithm is finished;

otherwise proceed with step (ii)

#### **Critical path**

- The critical path of a solution of the problem always comprises, in the given sequence, the following parts:
  - a head of some job,

2

- a sequence of jobs that are iteratively processed without interruption – at the considered stage, and
- finally, a tail of some job that is processed at the last position of the critical path
- In what follows, we derive the basic branching rule of the B&B procedure of Schrage by analyzing the critical path of the solution generated by the Schrage procedure
  - Business Computing and Operations Research WINFOR 419

Main result
4.3.3 Theorem
Let <i>L</i> be the makespan of the Schrage schedule (a). If this schedule is not optimal, there is a critical job c and a critical set <i>J</i> such that: $Ib(J) = \min_{i \in J} a_i + \sum_{i \in J} p_i + \min_{i \in J} q_i > L - p_c$
In an optimal schedule, either c is processed before all the jobs of J, or c will be processed after all the jobs of J (b). If this schedule is optimal, there exists J such that LB(J)=L
Stungeersking

#### **Proof of the Theorem**

- Let *G* be the disjunctive graph defining the considered problem with source 0 and sink *s*
- In addition, z is a critical path passing through a maximal number of jobs
- We modify the numbering of the jobs according to the definition of this path
- Therefore, the jobs processed on this path are numbered from 1 to p, i.e., the critical path is (0,1,2,3,...,p,s)

2

#### **Proof of the Theorem**

 At first, we prove that there is no processing between the times a<sub>1</sub>-1 and a<sub>1</sub>

- If there is a job processed in this interval, it would be finished at  $a_1$  since the processing of the first job starts just at this point of time
- If so and there is a job *j* processed there and we ask whether *a<sub>j</sub>*=t<sub>j</sub>. If so, we can extend the critical path. Obviously, this is not possible due to the assumption of a maximal path *z*
- However, if a<sub>j</sub><t<sub>i</sub> we know due to the processing of the Schrage procedure that there is an additional job processed just before j
- Clearly, because of that cognitions, we know that there is always a final job k with  $a_k=t_k$ . Note that this is at least the job firstly processed in the total schedule
- Hence, we have shown that there is no processing in the interval between  $a_1$ -1 and  $a_1$  due to the **maximum choice** of *z*

Business Computing and Operations Research WINFOR 422

#### **Proof of the Theorem**

• Secondly, we show  $a_1 = \min\{a_i \mid 1 \le i \le p\}$ 

2

- The machine was idle just before job 1 was processed
- Therefore, the Schrage procedure schedules no job in this interval and job 1 was scheduled subsequently
- I.e., all heads are larger than or equal to the head of job 1

Business Computing and Operations Research WINFOR 423

• Thus, we obviously obtain  $a_1 = \min\{a_i | 1 \le i \le p\}$ 

# Proof of the Theorem

 Thirdly, if q<sub>p</sub> is the minimal tail of all jobs 1,...,p, the length of the critical path becomes

$$L = a_1 + \sum_{i=1}^p p_i + q_p$$

$$= \min\{a_k \mid k \in \{1,...,p\}\} + \sum_{i=1}^p p_i + \min\{q_k \mid k \in \{1,...,p\}\}$$

 Hence, the lower bound and the solution value are equal, which immediately proves the optimality of the generated solution

#### **Proof of the Theorem**

- But, if otherwise q<sub>p</sub> is not the smallest tail of the jobs in {1,...,p}, there is always a job c with largest index whose tail is smaller than q<sub>p</sub>
- Let J={c+1,...,p} be the set of subsequently scheduled jobs on the critical path
- We know q<sub>c</sub><q<sub>r</sub> for all r in J and additionally a<sub>r</sub>>t<sub>c</sub> Why?
  - If a<sub>r</sub>≤t<sub>c</sub>, then, owing to its larger tail, job r would be scheduled before job c
  - Hence, we derive *a<sub>r</sub>>t<sub>c</sub>*

2

Business Computing and Operations Research

#### **Proof of the Theorem**

- Therefore, we have shown that the distance to the lower bound is smaller than  $\rho_{\rm c}$
- Thus, what can we learn from this constellation about the searching process?
- Is it necessary to consider constellations where job *c* is processed among set *J*?
  - Answer is NO!
  - Why? If we process *c* somewhere among the jobs of set *J*, the solution considered before cannot be improved since job *c*+1 cannot be processed until the point of time  $t_c$ +1 (due to  $a_{c+1}$ !). Therefore, the solution is deteriorated by at least one time unit since the position for *p* is optimal according to *J*
- Consequently, we have to decide about the scheduling position of *c* either before or after the set *J*

#### **Branching scheme**

- This leads directly to the following branching scheme of the algorithm
- Always proceed with the node resulting in the lowest bound found so far. The Lower Bound of a node S f(S) is always derived from the maximum of f(F) (*F*=Father node of *S*), LB(*J*), and LB({*C*} U *J*) A new node is added to the tree only if its lower bound is less than the upper bound  $f_0$  found so far
- Apply the Schrage procedure in each node If the solution is optimal, the procedure can be finished
  - and the optimal result is generated • Otherwise, compute *c* and *J* 
    - Generate the two additional subsequent nodes "c before J" (=Node 1) and "c after J" (=Node 2)
    - This can be easily conducted through an aimed modification of the considered instance
    - - Business Computing and Operations Research WINFOR 428

#### Node 1

After determining node c and the subsequent set J, we modify the tail of *c* in the following way:

$$q_c = \max\left\{q_c, \sum_{r \in J} p_r + q_p\right\}$$

2

By doing so, the execution of the Schrage procedure always results in a constellation where c is processed before all jobs placed in set J.

Additionally, the algorithm "knows" the extended tail of c to process this job potentially earlier

#### Node 2

After determining node c and the subsequent set J, we modify the head of *c* in the following way:

$$a_c = \max \left\{ a_c, \min\{a_r \mid r \in J\} + \sum_{r \in J} p_r \right\}$$

By doing so, the execution of the Schrage procedure always results in a constellation where *c* is processed after all jobs placed in set J.

Additionally, the algorithm "knows" the extended head of c to process other jobs potentially earlier

#### Bound computation and Schrage procedure

- Carlier proposes a specific technique to be able to execute the Schrage procedure in O(n log n) time
- **Upper bound computation**: Every time the Schrage procedure is applied, the generated makespan is compared with the current upper bound f<sub>0</sub>. Moreover, an alternative constellation conserving the order of all jobs except for job *c*, which is processed after *J*, is additionally compared with this upper bound
- An additional lower bound is derived from the application of the Schrage procedure with allowed preemptions

2

Business Computing and Operations Research WINFOR 431

#### Preemption

- The preemption version of the Schrage algorithm makes use of the greedy rule of the original Schrage procedure, but can additionally preempt each processed job whenever another one arrives with a larger tail
- It is trivial to show that the generated solution is always optimal and is therefore a Lower Bound of the original problem
- In addition, for example, by using heap data structures, this procedure can be executed again in O(n log n) steps

Business Computing and Operations Research WINFOR 432

#### **Computational results**

- This procedure was coded in FORTRAN on an IRIS 80
  and initially tested on 1000 problems
- For each problem with n jobs, 3 n integers with uniform distributions between 1 and  $a_{max}$ , 1 and  $p_{max}$  as well as 1 and  $q_{max}$  were respectively drawn
- 20 different values for *n* were tested; *n*=50, 100, 150, 200,..., 1.000
- Further details can be found in Carlier (1982)
- 999 problems were solved optimally
- One problem with *n*=850 was not solved (but the distance to bound was 2!). The lower bound was 29.800 (UB=29.802)
- In most cases the solution process takes only a small amount of time (extreme small-sized solution trees)

# Analyzing the constellation

- *c*=3 and *J*={2}
- LB(J)=min{13}+6+min{26}=45
- LB({2,3})=11+6+7+24=48
- Therefore, we inherit the Lower Bound of the father node. This is LB=49
- UB=50

2

- Now, we have to branch again
  - c before J
  - *c* after *J*

• New problem constellation $\begin{array}{r rrrrrrrrrrrrrrrrrrrrrrrrrrrrrrrrrrr$			c af	ter	J

#### 4.4 Multiple stages

- If M>1, each objective function itemized in Section 4.2 leads to an NP-complete problem for the general job-shop system case
- Therefore, a huge set of different heuristics can be found in literature
- Owing to its simple representation in disjunctive graphs, the minimization of the cycle time or the makespan is frequently pursued
- In comparison to other NP-complete problems, the jobshop problem belongs to the most complex ones. This results from the fact that most efficient exact procedures are not able to solve even small-sized problems in a reasonable time (e.g., 10 jobs on 10 machines)

2

Business Computing and Operations Research WINFOR 449

#### 4.4.1 Use of priority rules

- A more intuitive approach can be the application of dynamic rules deciding about the sequence on every machine
- Therefore, in case of an idle machine, this rule decides about the next job to be scheduled by selecting one of the waiting jobs
- Note that this approach is very flexible since it can also be applied to dynamic problems while its complexity only depends on the defined computation of the integrated priority rule
- Frequently, the SPT and its variants integrated into specific hierarchies are applied

Business Computing and Operations Research WINFOR 450

#### 4.4.2 Elaborated heuristics

Well-known approaches are for example

- The Shifting Bottleneck Procedure (SBP) of Adams, Balas and Zawack
- The Tabu Search procedure of Nowicki and Smutnicki

#### 4.4.2.1 The Shifting Bottleneck Procedure

- This procedure can be applied to arbitrary Mstaged job-shop systems to minimize the cycle time
- It makes use of the Branch&Bound algorithm of Carlier as a subroutine
- The problem description is defined as a disjunctive graph
- The bottleneck machine of the total schedule is considered to be planned more accurately in each step

2

2

Business Computing and Operations Research WINFOR 452

#### **Basic attributes**

- The machines are sequenced one at a time, consecutively
- In order to do so, a one-machine scheduling problem with head and tails is optimally solved for each not yet sequenced machine
- This result is taken as rank of the machine to decide about its necessity to sequence it permanently. After sequencing the current machine, all machines sequenced before are resequenced optimally due to the modified heads and tails
- The one-machine problems with head and tails are constructed out of the modified disjunctive graph

#### **Deriving one-machine problems**

Let  $M_0 \subset M$  be the set of machines that have already been sequenced by choosing selections  $S_p(p \in M_0)$ . For any  $k \in M \setminus M_0$ , let  $(P(k, M_0))$ be the problem obtained from the original problem definition replacing each disjunctive arc set  $E_p(p \in M_0)$ by the corresponding selection  $S_p(p \in M_0)$  and deleting each disjunctive arc set  $E_p(p \in M \setminus M_0, p \neq k)$
#### The procedure

- 1.  $M_0=\emptyset$  (set of already sequenced machines)
- Identify a bottleneck machine *m* among the machines *k* in *MM*<sub>0</sub> and sequence it optimally by applying the Carlier algorithm. Set *M*<sub>0</sub>=*M*<sub>0</sub>U{*m*}
- 3. Reoptimize the sequence of each critical machine *k* in  $M_0$  in turn while keeping the other sequences fixed, i.e., set  $M^0=M_0\backslash\{k\}$  and solve  $P(k,M^0)$ . Then, if  $M_0=M$ , stop; otherwise go to step 2

2

Reoptimization processes

Business Computing and Operations Research WINFOR 455

- The reoptimization process is repeated at most three times for sets  $|M_0| < |M|$  in every iteration
- Every time a full cycle is completed, the elements of  $M_0$  are reordered according to the non-increasing values of the solutions of the respective one-machine problems with heads and tails
- In the last step, when |M<sub>0</sub>|=|M|, we continue the local reoptimization process to the point where no more improvement for a full cycle occurs

Business Computing and Operations Research WINFOR 456

#### **Two versions**

- Two different versions of the SBP are proposed by Balas et al.
  - The first version operates as described above
  - The second one applies the SBP to the nodes of a searching tree generating several solutions simultaneously, i.e., in each branching step, alternative constellations are generated to increase algorithm diversification

#### The second SBP-version

- The process starts again with the node defined by  $M_0=\emptyset$
- In each branching step, in a node on level  $|E|M_0|$ , the f(*l*) machines with the largest respective machine objective value out of  $MM_0$  are processed as alternative child nodes. Note that f is a monotonous decreasing function reducing the branching degree in the levels that are generated later.
- A second instrument for limiting the size of the branching tree is a penalty function – defined for every node – that penalizes the choices made at different levels in generating the node in question, in proportion to their deviation from the bottleneck, and with a weighting that is heavier for the higher than for the lower levels of the tree. Whenever the value of the penalty function for a node exceeds a predetermined limit, the node is discarded

Business Computing and Operations Research WINFOR 458

#### Combined breadth-first / depth-first

- For the first *I*<sup>\*</sup>=*M*<sup>1/2</sup> levels, the breadth first search is used to produce all successors according to the function f, i.e., a full tree over *I*<sup>\*</sup> is generated
- In the second part of the procedure, the nodes are clustered into groups of size *f(<sup>k</sup>)*, containing the successors of level *k*. Subsequently, the depth-first searching phase starts. In this phase, the highest ranking member of one of the groups is chosen and explored straight to the bottom of the search tree, or as far as the penalty function permits
- The current best solution is always stored as an upper bound. Hence, branches, which reach the upper bound, are fathomed. After ending this exploration, the highest rank member of another group of nodes is chosen

Business Computing and Operations Research WINFOR 501

#### **Rescheduling Machine 1**

- The sequence of Machine 1 is kept unchanged!
- 1 2 3 is the chosen sequence!

#### **Priority rule application**

In order to rate the solution quality of the SBP versions, different priority rules are applied in a specific constellation. The applied rules are • FCFS (=First Come First Serve)

- LST (=Late Start Time)
- EFT (=Early Finish Time)
- LFT (=Late Finish Time)
- MINSLK (=Minimum Slack)
- SPT (=Shortest Processing Time)
- LPT (=Longest Processing Time)
- MIS (=Most Immediate Successors)
- FA (=First Available)
- RANDOM
- 2

Business Computing and Operations Research WINFOR 506

#### **Computational results**

- Procedures were implemented in FORTRAN on a VAX 780/11 on 40 problems taken from wellknown benchmarks
- In what follows, we depict the results presented by Balas et al.
- They tested the SBP in its both variants against some simple priority rules
- The consumed CPU time is illustrated in the tables beside the solution quality

Business Computing and Operations Research WINFOR 507

#### **Priority rule application**

- First, the priority rule algorithms are applied in a straightforward fashion
- Second, the priority rules are applied in a random fashion by applying all rules
  - The randomized rule is to select one of the available operations to be processed next randomly
  - This is done by applying a probability distribution which makes the odds of being selected proportional to the priority assigned to each operation by the given dispatching rule
  - The run is repeated until ten consecutive runs produce no improvement, and the best result obtained is reported as the procedure's output

#### **Main results**

#### Priority rules:

- No domination between the rules can be identified
- Eight of the ten rules showed best result on at least one problem
- Two rules (LPT and FA) never
- Priority rules vs. SBP I/II
  - In 38 cases SBP I finds better solutions than the constellations generated by the priority rule procedure whether in the straight or randomized version
  - Furthermore, Version 2 finds substantially improved solutions for many constellations most of the time
    Altogether, it can be stated that SBP II is always without exception at least as good as the randomized priority rule

  - · Moreover, in the vast majority of the considered cases, it is considerably better
  - Typical average improvement rates were between 4 and 10 percent Business Computing and Operations Research WINFOR 513

#### SBP – Pros and Cons

#### Pros

- Elaborated procedure
- Despite the fact that the procedure uses a Branch&Bound procedure to tackle an NP-hard problem as a frequently called subroutine, it is quite fast in comparison to well-known meta strategies, as for example, the Tabu Search procedure of Nowicki and Smutnicki
- SBP I is frequently used as an initial procedure to generate a first solution with quite good quality

Cons

2

- · Solution quality is poorer than known from elaborated meta strategies
- · Single priority rules are much faster

#### 4.4.2.2 Tabu Search by Nowicki-Smutnicki

- Besides the SBP as well as various Branch&Bound-procedures, meta heuristics have recently been developed for the job-shop scheduling problem with makespan objective
- A very efficient and relatively easy to implement algorithm is the Tabu Search (TS) procedure introduced by Nowicki and Smutnicki in 1996
- The algorithm bases on the disjunctive graph and tries to reduce the problems makespan iteratively by changing the job sequence within the critical path

Business Computing and Operations Research WINFOR 515

2

#### **Neighborhood Search**

- Tabu Search methods are based on Neighborhood Search, a local search method.
- Given a solution s, a Neighborhood Search creates out of a solution  $\pi$  a new solution  $\pi$ ' by manipulating  $\pi$ ; this operation is called a **move**.
- The set of moves applicable on a given solution s is called the neighborhood  $N(\pi)$ . Neighborhood Search selects the best move in  $N(\pi)$  and applies it.
- If a solution can be represented as a permutation of numbers, common Neighborhood Search moves are swaps and shifts within this permutation.

Business Computing and Operations Research WINFOR 516

#### **Critical path**

- Let  $u = (u_1, \dots, u_w)$  denote the critical path, with w the number of operations on a longest path within the directed disjunctive graph
- The path can be divided into **blocks**  $B_1, ..., B_r$  with the following attributes:
  - $B_i = (u_{ai}, u_{ai+1}, ..., u_{bi})$  and
  - $1 = a_1 \le b_1 < b_1 + 1 = a_2 \le b_2 < b_2 + 1 = a_3 \le \dots \le a_r \le b_r = w$
  - B<sub>i</sub> contains all operations processed on the same machine (*i* = 1, ..., *r*)
  - Two consecutive blocks contain operations processed on different machines, *i.e.*,  $\mu(B_i) \neq \mu(B_{i+1})$ , i = 1, ..., r-1

#### The applied neighborhood

- The size of the neighborhood plays an important role.
- Thus, Nowicki and Smutnicki introduced a reduced neighborhood with the following moves:
- In block B<sub>1</sub> the last two operations are permutated
- In block  $B_2$  to  $B_{r,1}$  the first two operations and,

2

if a<sub>i</sub><b<sub>i</sub>, the last two operations are permuted
In block B<sub>r</sub> the first two operations are permutated

#### Remark to the critical path

One might argue that the critical path is not well-defined. But numerical results showed that the selection of one critical path has a minor influence in regard to the solutions quality.

 $\rightarrow$  An arbitrary critical path can be chosen.

2

#### Tabu List

- A major drawback of local search procedures, such as hill-climbing, is cycling between two solutions and only returning a local optimal solution
   In order to avoid cycling within the searching process,
- In order to avoid cycling within the searching process, Tabu Search algorithms use a short time memory of blocked moves, called Tabu List
- If a move v=(x,y) is performed, the inverse move v'=(y,x) is added to the Tabu List

2

• The Tabu List has a given size *maxt*, and it contains the inverse moves of the moves applied in the last *maxt* iterations

Business Computing and Operations Research WINFOR 524

#### **Aspiration criterion**

- To secure that promising moves are not blocked, Nowicki and Smutnicki divide the set operations in the Tabu List into subsets *UP* and *UNP*
- UP contains all blocked moves leading to a better solution than the ones visited in all past iterations (profitable moves)
- UNP consists of all blocked non-profitable moves
- A criterion, called aspiration criterion, allows the search to perform a profitable move although it belongs to the Tabu List.

Business Computing and Operations Research WINFOR 525

#### Long time memory

- If a solution possesses a good objective function value, it is likely that its neighbors contain good objective function values as well
- Since from a given solution with small objective function value only the best move was chosen, the observation of other neighbors was discarded although they could guide into regions with good solutions, too
- To take this thought into account, Nowicki and Smutnicki proposed to embed their procedure into a guided super routine by storing the solutions with the lowest objective function values within a list *L*
- The elements of *L* consist of the permutation  $\pi$  for the given solution, a modified neighborhood  $N(\pi) \setminus \{v'\}$  (*v*' is the already applied move), and the Tabu List *T*

#### Nowicki and Smutnicki – Summary

- The procedure is a solution method for solving the jobshop scheduling problem with makespan objective which is relatively easy
- It substantially intensifies the searching process in promising regions, evaluates the neighborhoods in the single steps very fast, and the authors can improve the best known makespan for difficult problem instances in many cases
- In 2005, Nowicki and Smutnicki propose a further advanced Tabu Search procedure with improved diversification (long term behavior)

2

• Additionally, they propose an improved starting heuristic in order to construct a suitable starting solution

#### 4.5 Flow-shop problems

- In the following, we consider flow-shop problems as a special case of job-shop systems
- In this special case, each job has an identical machine sequence in which it is processed
- Therefore, we can define a definite numbering (1,...,M) of the used resources that determine the processing sequence of each job
- Despite the fact that the total solution space still consists of altogether (*N*!)<sup>M</sup> constellations, this problem seems to be somehow relaxed in comparison to the general jobshop problem

Business Computing and Operations Research

The dominance criteria

#### The first dominance criterion:

2

In an M-staged flow-shop system, there is always an optimal solution minimizing the makespan where the scheduling on the first two machines is identical. This is also true for the minimization of the total lead time.

Business Computing and Operations Research \_531

#### Proof of the first dominance criterion

- Let us assume there are unequal sequences that are processed on the first two machines
- Let 1 2 3 ... N be the job sequence applied to machine 2
- We define t as the first (lowest numbered) position in this job sequence where a difference between the sequences on machine 1 and machine 2 arises
- Therefore, we have the sequence 1 2 3 ... t-1 l with *b* t at the first stage
- In what follows, we consider an alternative constellation by exchanging t and / on machine 1

#### **Consequences for jobs**

#### Job t .

- •
- The exchange on machine 1 can improve only the subsequent constellation by an earlier processing at stage 2 Therefore, the remaining schedule is of better or at least of an equal quality .

#### Job I

.

2

- Job I
  Firstly, note that the end of processing of job / at stage 1 in the modified constellation is equal to the point of time the processing of job *t* ends at stage 1 in the original constellation. Let *c* denote this point of time in both schedules
  Therefore, job / can not be processed at stage 2 before *t* is processed. Note that this applies to both schedules
  Schedule 1: Reason: Processing of job *t* at stage 2 before *t* is point *t* addition, job *t* at stage 2 has to wait for its processing at stage 1, which is not ended before *c*Schedule 2: Reason: Processing of job *t* at stage 1. In detail, job / at stage 2 has to wait for its processing at stage 1, which is not ended before *c*

#### Conclusions

- The processing times of job t and job / at stage 2 are not influenced by the executed exchange
- · No effect on the total makespan as well as on the resulting cycle time
- · This completes the proof

#### The dominance criteria

#### The second dominance criterion:

2

2

In an M-staged flow-shop system there is always an optimal solution generating the minimal makespan where the scheduling on the last two machines is identical

Business Computing and Operations Research WINFOR 536

Business Computing and Operations Research WINFOR 537

# Proof of the second dominance criterion Again, we assume that there is no equal sequence at the last two stages In detail, we assume that the sequence 1 - 2 - 3 - ... - *N* is processed on machine *M*-1 Let *t* be the minimal number of a job where the sequences at stages *M*-1 and *M* differ, i.e., 1 - 2 - 3 - ... - *I*, with *I*>*t* is processed on machine *M*Now, we consider an alternative constellation where we exchange job *I* and job *t* at the last stage

#### Consequences

- Optimal Schedule
  - Let x be the beginning of the processing of job I at stage M while y denotes the end of processing of job I at stage M-1
  - We know x≥y
  - We have cycle time C
- Alternative Schedule
  - In order to compute the makespan for this schedule, we know that nothing is lost due to the executed exchange of I and t
  - Moreover, there is no side-effect on the jobs processed after job t, wherefore the new cycle time C' is lower than or equal to c

Business Computing and Operations Research WINFOR 539

This completes the proof

2

#### 4.5.1 The procedure of Johnson

- In what follows, we consider the special case of the flow-shop problem where only production stages are given
- Note that already this quite simple constellation is an NP-complete problem for the general job-shop case
- In contrast to this, we will present a very efficient algorithm generating an optimal schedule for the 2-staged flow-shop problem in O(N log N) steps: the so-called **Johnson algorithm**. This algorithm determines the schedule with the minimal makespan

#### 

#### Changing the sequence in 2/3-FS

#### 4.5.1.1 Theorem

For the two- or three-staged flow-shop with the objective of makespan minimization, there is always an optimal solution that has equal scheduling sequences on all machines

#### **Proof of the Theorem**

- Clearly, we may apply the two dominance criteria
- Thus, the claim of the Theorem follows
- immediately as a corollary of both criteria
- This completes the proof

# 4.5.1.2 Algorithm (Johnson)

Business Computing and Operations Research WINFOR 542

Initialization:  $R = \{1, 2, 3, ..., N\}$  is the list of all jobs to be scheduled

1. Determine job  $\hat{n}$  by:

2

 $\min\{p_{1,\hat{n}}, p_{2,\hat{n}}\} = \min\{p_{1,n}, p_{2,n} \mid 1 \le n \le N\}$ 

2. If  $p_{1,\hat{n}} = \min\{p_{1,\hat{n}}, p_{2,\hat{n}}\},\$ 

2

then  $\hat{n}$  is placed on the next available position at the top of the current schedule; otherwise  $\hat{n}$  is placed on the next available position at the

end of the current schedule

3. Delete  $\hat{n}$  from the list of jobs to be processed in the schedule

4. Proceed with step 1 until the list of remaining jobs *R* is empty

#### The proof of optimality

#### 4.5.1.3 Theorem

2

Algorithm 4.5.1.2 generates an optimal solution for the makespan minimization problem in a twostaged flow-shop production system

Computing the total sum of waiting times  

$$\sum_{i=1}^{N} I_i = \sum_{i=1}^{N} \max\left\{\sum_{k=1}^{i} p_{1,k} - \sum_{k=1}^{i-1} I_k - \sum_{k=1}^{i-1} p_{2,k}, 0\right\}$$
Lemma:  

$$\sum_{i=1}^{N} I_i = \max\left\{\sum_{i=1}^{k} p_{1,i} - \sum_{i=1}^{k-1} p_{2,i} | 1 \le k \le N\right\}$$

#### Intermediate summary

- A found solution can only influence waiting times on machine 2 to minimize the makespan
- We have generated a compact form for computing all resulting waiting times on machine 2

#### Transformation

- Note that in the algorithm of Johnson it would have been processed after i+1
- Now, we generate schedule T out of S by exchanging the jobs i and i+1

2

 Owing to this simple modification, we can easily derive the new updated objective function by computing the new Y<sub>k</sub>-values

$$\begin{aligned} & \mathcal{F}_{k=1}^{i-1} p_{1,k} - \sum_{k=1}^{i-1} p_{2,k} + p_{1,i+1} + \max\{p_{1,i} - p_{2,i+1}, 0\} \\ & \mathcal{F}_{k=1} \sum_{k=1}^{i-1} p_{1,k} - \sum_{k=1}^{i-1} p_{2,k} + p_{1,i} + \max\{0, p_{1,i+1} - p_{2,i}\} \\ & \mathcal{F}_{k=1} \sum_{k=1}^{i-1} p_{1,k} - \sum_{k=1}^{i-1} p_{2,k} + p_{1,i} + \max\{0, p_{1,i+1} - p_{2,i}\} \\ & \mathcal{F}_{k=1} \sum_{k=1}^{i-1} p_{1,k} - \sum_{k=1}^{i-1} p_{2,k} + p_{1,i+1} + p_{1,i} - p_{2,i+1} \\ & \mathcal{F}_{k=1} \sum_{k=1}^{i-1} p_{1,k} - \sum_{k=1}^{i-1} p_{2,k} + p_{1,i+1} + p_{1,i-1} - p_{2,i+1} \\ & = \sum_{k=1}^{i-1} p_{1,k} - \sum_{k=1}^{i-1} p_{2,k} + p_{1,i} + p_{1,i+1} - p_{2,i+1} \end{aligned}$$

## Conclusion

- T is not worse than S in both cases
- As a consequence, each optimal schedule can be transformed into a Johnson schedule without losing its optimality

Business Computing and Operations Research WINFOR 563

- This completes the proof

2

Example
<ul> <li>Given: 2 Machines A and B, and 5 jobs to be processed</li> <li>Processing times</li> </ul>

Machine			Jobs						
	1	2	3	4	5				
A	20	11	13	5	17				
В	15	15 27 8 27 13							

## Steps of Johnson's algorithm

- 1. Minimum is 4 on A
- Consequence: First possible position (4,-,-,-,-)
- 2. Minimum is 3 on B Consequence: Last possible position (4,-,-,-,3)
- 3. Minimum is 2 on A
- Consequence: First possible position
- (4,2,-,-,3) 4. Minimum is 5 on B

2

- Consequence: Last possible position (4,2,-,5,3)
- 5. Complete optimal schedule is (4,2,1,5,3)

• Now, we consider the general case M>2

2

2

Unfortunately, it was shown that these problems are NP-hard

Business Computing and Operations Research \_\_\_\_\_\_\_566

• Therefore, we introduce a simple heuristic approach in the following

<section-header><list-item><list-item><list-item><list-item><list-item>

## Palmer's heuristic

 $\begin{aligned} \forall j \in \{1, \dots, N\} : s_j &= \sum_{k=1}^{M} \left( M - 2 \cdot (k-1) - 1 \right) \cdot t_{j,M-k+1} \\ \Rightarrow M &= 2 : \\ s_j &= (2 - 2 \cdot 0 - 1) \cdot t_{j,2} + (2 - 2 \cdot 1 - 1) \cdot t_{j,1} = t_{j,2} - t_{j,1} \\ \Rightarrow M &= 3 : \\ s_j &= (3 - 2 \cdot 0 - 1) \cdot t_{j,3} + (3 - 2 \cdot 1 - 1) \cdot t_{j,2} + (3 - 2 \cdot 2 - 1) \cdot t_{j,1} \\ &= 2 \cdot t_{j,3} + 0 \cdot t_{j,2} - 2 \cdot t_{j,1} \\ \Rightarrow M &= 4 : \\ s_j &= (4 - 2 \cdot 0 - 1) \cdot t_{j,4} + (4 - 2 \cdot 1 - 1) \cdot t_{j,3} + (4 - 2 \cdot 2 - 1) \cdot t_{j,2} + (4 - 2 \cdot 3 - 1) \cdot t_{j,1} \\ &= 3 \cdot t_{j,4} + t_{j,3} - t_{j,2} - 3 \cdot t_{j,1} \end{aligned}$ 

Solution
<ul> <li>The jobs are scheduled in sequence of non-increasing priority</li> <li>Generates only solutions with an equal sequence at all stages</li> </ul>

### **CDS Heuristic**

- CDS="Cambel Dudek Smith", the authors of the respective paper
- Extension of the Johnson algorithm for multiple-stage cases
- Considers only solutions with equal sequences at all stages
- Note that it starts from at least four stages

- Note that it starts from at least four stages Generates artificial 2-staged problems out of the general constellation and solves them optimally by the application of the Johnson algorithm For M=2 the CDS procedure becomes the Johnson algorithm generating an optimal solution Otherwise, the procedure generates M-1 iterations representing an additional two-staged flow-shop problem Can be used for the minimization of cycle time or total lead time
- lead time 2 Business Computing and Operations Research WINFOR 573

 Compute the processing time for all jobs j=1,...,N on the two machines in the k-th auxiliary problem:

$$\boldsymbol{\Theta}_{j,2}^{k} = \sum_{i=M-k+1}^{M} t_{j,i}$$

- 6. Solve the problem with the Johnson algorithm
- Check if k<p. If so, set k=k+1, go to step 3; Otherwise proceed with step 8
- Use the original problem to compute the objective value of all p generated solutions
- 9. Select best result as the output of the procedure
  - Business Computing and Operations Research WINFOR 575

## **Pros and Cons**

- Pros
  - CDS/Palmer are fast to compute
  - CDS generates quite good solutions
- Cons

2

- Poor results in comparison to elaborated meta strategies
- Used for finding an initial solution but not for the final result
